

## Investment Grade

# Drastic Yields Require New Spread Measures

| CORE

With the decline in all-in yields driving bond prices to near all-time highs, traditional spread measures do not appropriately capture the risk/reward of corporate debt. We recommend investors use BCDS spread, a measure that adjusts for recovery differences across different \$px bonds, to assess relative value in credit.

The credit spreads widening over the past few weeks has been more than offset by the rally in Treasuries, with both 10y and 30y yields falling more than 100bp this year, despite the reversal yesterday. As a result, the yield on the Bloomberg Barclays US Corporate Index has declined to 2.6%, near an all-time low. The same is true for the Long Index, which now yields less than 3.3%. This has driven bond prices higher, with the Long Index trading above \$129. Indeed, within 10y+ bonds, only 8% of bonds trade below par and only a further 10% of bonds trade between par and \$110, a drastic difference from March 2016, when spreads were equally wide but the prices of the bonds were nowhere near the same.

The significant portion of corporate bonds – especially in the long end – trading meaningfully over par calls into question the efficacy of traditional spread measures. Specifically, the regular yield and spread (OAS or g-spread/z-spread) measures assume that a bond pays all of its

This document is intended for institutional investors and is not subject to all of the independence and disclosure standards applicable to debt research reports prepared for retail investors under U.S. FINRA Rule 2242. Barclays trades the securities covered in this report for its own account and on a discretionary basis on behalf of certain clients. Such trading interests may be contrary to the recommendations offered in this report.

coupons and principal. The yield (and spread) is then calculated based on the discount factor such that the present value of these future cash flows equals the current price. While they are a good measure of the cash-on-cash return, we believe they do not appropriately capture the risk/reward of corporate debt in the current environment.

Specifically, because the traditional spread measures do not explicitly model the outcome in which a bond defaults, they are agnostic to differences in the effective loss given default (LGD) of securities with different prices. They do not incorporate the fact that a bond trading at a premium has a higher LGD than a lower-priced bond, all else equal. For instance, assuming 40% recovery, a par bond would have an effective 60% loss given default, while a bond trading at \$120 would have a 66.7% loss, which should mean that the latter trades at a wider spread. Market participants do factor for this risk using back-of-the-envelope adjustments (say, 1bp/\$), but they are approximate at best. Specifically, unlike the fixed dollar price adjustment, the effective compensation for differences in dollar price is not in fact linear.

1. The difference in loss (assuming 40% recovery) given default for an \$80 and \$100 price bond is 10% (60% LGD for par bond versus 50% for \$80 security), while it is less than 5% for a \$120 and \$140 bond pair, which would suggest that the basis between the latter pair should be lower.
2. The adjustment for price also increases with underlying spread (premium debt of wider trading credits should trade at a larger discount), as well as maturity (longer-dated bonds should offer higher compensation per \$ of premium than short-term debt). See [Dollars and Sense](#) for more details.

In addition to having higher LGD, the risk of high-coupon paper becomes evident in a few other scenarios. As we discuss in [High Price Bonds Beware of New Issue](#) and [Large Angels Fall Harder but Bounce Higher](#), high dollar price debt tends to perform worse than par paper around new issuance, as well as on downgrade to high yield (which was also evident in the recent underperformance of high-coupon KHC debt). Given the recent spread widening – which means that the premium for high \$px bonds should be higher – and the fact that the Long Index is trading at an all-time high in price, we believe market participants should use a more formal model to account for differences in \$px. Specifically, we recommend using BCDS spreads, which account for differences in coupon and, in our opinion, are a better measure of credit risk in the current environment.

The BCDS spread is calculated as follows: on each payment date (coupon or principal), the bond is assumed to either 1) make the payment or 2) default and pay the expected recovery. The total return from the bond is the sum of the two cash flows weighted by the survival probability on each payment date. The survival probability curve and, through it, the BCDS spread are then calculated by calibrating the cash flows to the current price of the bond. Since this measure explicitly models the default outcome, it accounts for the difference in LGD across different dollar price debt.

Using BCDS instead of traditional spread measures has a few implications. First, given that the Bloomberg Barclays Index trades at a more than \$11 premium, the BCDS spread is nearly 10bp tighter than L-OAS.<sup>1</sup> The adjustment is not uniform across maturity buckets. Longer-dated bonds trade at a higher premium over par; therefore, BCDS spreads are as much as 20bp tighter (Figure 2).

Another key implication of this is that 10s30s curves are indeed flatter than they appear. This is especially true for A rated corporates, given that their 30y debt trades at a significant premium. Indeed, while the 10s30s OAS curve is 30bp, the curve on a price-adjusted basis is only 17bp. This reinforces our view that 10s30s, especially for A credits, look too flat and should steepen,

<sup>1</sup> Note the because BCDS is calculated off the swap curve, it is most comparable to Libor OAS.

especially given the decline in yields. Figure 3 shows the average 10s30s curves for A and BBB industrials in both OAS and BCDS terms. Although BBB curves look steep even after the adjustment for price, we note that high-coupon BBB- debt is exposed to significant downside in case of a downgrade to high yield. We highlight select high coupon BBB- bonds that screen as especially rich in *The Highs and Lows of High Price Bonds*.

**FIGURE 2. Spread Adjustment for Dollar Price by Maturity Buckets**

Source: Bloomberg, Barclays Research

**FIGURE 3. 10s30s OAS and BCDS Curves**

Note: For industrials only.  
Source: Bloomberg, Barclays Research

Furthermore, using BCDS spreads also changes the relative value opportunity set. While in nominal spread terms high dollar price bonds appear to offer more compensation, after adjusting for dollar price, the relative cheapness/richness in some cases can completely flip. One such occurrence is in long-dated Charter bonds, shown in Figure 4, where the highest price 2045s offers the most spread compensation in OAS terms but the lower price 2050s are the cheapest when using BCDS.

BCDS spreads can be found on “[Bond Screening Tool](#)” on Barclays Live and is available for most index-eligible bonds. The BCDS spread is calculated off the swap curve and is therefore most comparable to L-OAS. The difference between L-OAS and BCDS is the effective spread compensation for dollar price.
